A chimeric antigen receptor-expressing T cell that targets and kills TIM3 expressing cancers such as acute myeloid leukemia (AML). The CAR construct works by using a novel anti-TIM3 scFv region to enable T cell targeting of TIM3 expressing cancer cells and T-cell activation through the incorporation of co-stimulator and intracellular signaling regions. TIM3 is overexpressed on AML cells. Because TIM3 is also a leukemic stem cell surface marker in 85-90% of AML subtypes and is not expressed in normal hematopoietic stem cells, the TIM3 CAR-T cells might also kill leukemic stem cells leading to a lower probability that minimum residual disease might lead to AML recurrence.

COMMERCIAL OPPORTUNITY

- AML is a type of blood cancer where the bone marrow makes abnormal myeloblasts. AML accounts for nearly one-third of all new leukemia cases each year. The American Cancer Society estimates that in 2017: 21,380 patients will develop AML and 10,590 AML patients will die.
- The standard of care for AML treatment has changed little over the past four decades. Intensive chemotherapy followed by hematopoietic stem cell transplantation remains the most effective treatment. However, most newly diagnosed elderly patients are ineligible for intensive chemotherapy, and there are no effective second line treatment for patients with relapse/refractory disease. As a result, the 5-year overall survival rates is 27%, and is less than 10% for patients over age 60. It is anticipated that the existing treatment for around 17,000 newly diagnosed AML patients will not be effective.
- AML cells and AML leukemic stem cells have been shown to have an almost ten-fold greater expression of TIM3 than normal cells. AML resistance and relapse to chemotherapies may originate from leukemic stem cells (LSCs), so targeting and eradicating LSCs might improve AML patient survival.
- The marketplace is attractive for CAR-T development, as there are 27 current CAR-T clinical trials being carried out by companies including Kite Pharma (market cap $2.3B), Juno Therapeutics (market cap $2.0B), Cellectis (market cap $614.4M), and Bluebird Bio (market cap $2.9B). Several of these CAR-T therapies have received breakthrough therapy designation allowing priority review by the FDA.

TECHNOLOGY

Anti-TIM3 sequences were identified by a next generation sequencing screening coupled with a monoclonal antibody producing procedure. This screening procedure for identifying anti-TIM3 sequences involved: 1) immunizing mice, 2) isolating splenic B cells, 3) isolating RNA, 4) FuzeSeq™ (GENEWIZ) antibody sequencing, 5) analyzing bioinformatics data of IgH and IgL rearrangements to select putative anti-TIM3 sequences based on frequency, and 6) in vitro screening to validate the clones. Two scFv VH domains, IGHV812 and IGHV1S81, and four scFv VL domains, IGKV1385, IGKV539, IGKV486, and IGKV461 were selected as top polypeptides candidates. In vitro experiments showed that co-culturing TIM3 positive cancer cells with Jurkat T cells transduced with synthetic anti-TIM3 scFv regions elicited T-cell activation. The percentages of activated T-cells were measured by IFN-γ levels using flow cytometry, and were strongest for IGHV812-IGKV461 with 47.3%, and IGHV812-IGKV486 with 53.8%. CAR constructs have been designed to target and kill TIM3-expressing cancer cells.

PUBLICATION/PATENT

- Provisional Patent filed for Dr. Marco Davila in February 2017.
